
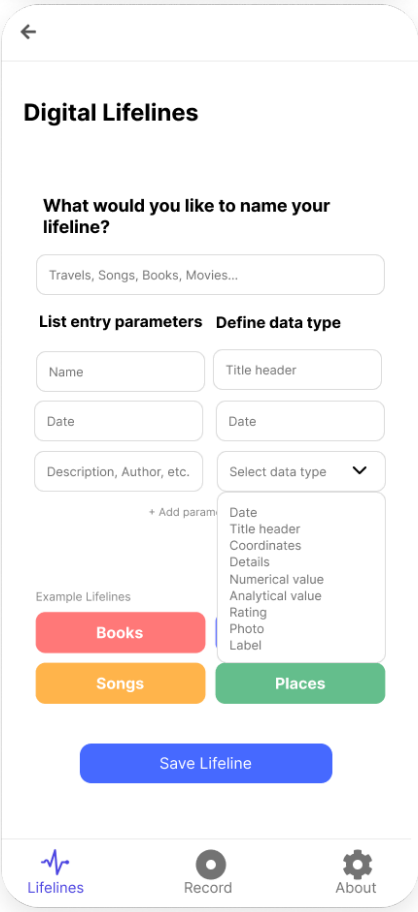
This is the landing page the user will see when they download the app for the first time. They can either import a JSON file that specifies the specific fields/information they would like to record for a new timeline. Or they can create a custom timeline using the GUI.

When the user imports a JSON file, it should follow a specific format so that the app is able to read it and create a custom GUI according to information in the JSON file.

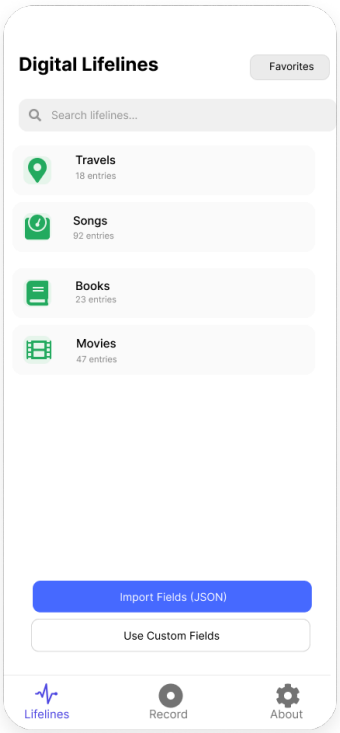


If the user decides to use the GUI interface, they will be directed to enter the name of the lifeline they want to create, any fields (denoted by “parameters” in the graphic to the left) they want to include, as well as the respective data types. The user can add however many fields they feel are necessary.

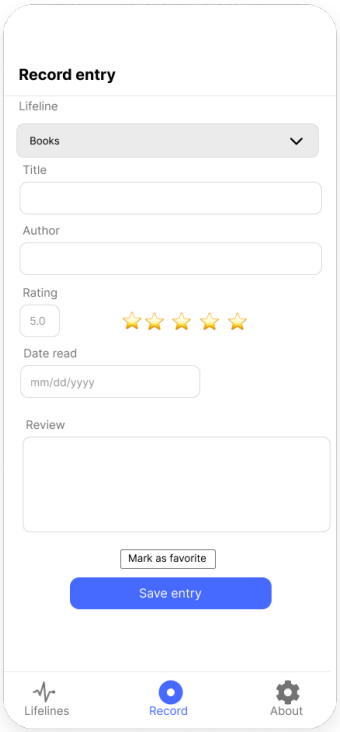
When users are entering their desired fields, the app shows suggestions to the user for inspiration. It subtly suggests fields such as “Description”, “Author”, etc.

Users are asked to specify the data types for their respective fields so that when they add an entry for the timeline, the fields are formatted properly. They can specify that data be a date, a title header, coordinates, details, a numerical value, an analytical value (combination of both digits and alphabets. For example, 120/80 mmHg), a rating, a photo, or a label.

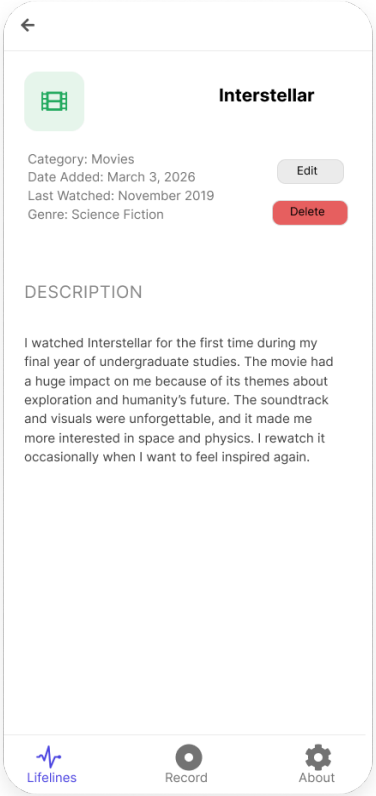
Currently, timelines may be created without any fields if the user wants. But in the future, the user may be required to create at least a “Name” and a “Date” field for all lifelines (the “Date” field could be changed to say “Date read”, “Date watched”, etc. depending on what the user prefers, and the “Name” field could be changed to “Title” or “Place” depending on what the user prefers as well). The app provides example lifelines that the user can refer to for inspiration.



The home page becomes populated with lifelines as the user continues adding them. Users still have the option to import their own JSON files or use the GUI. Metadata of how many entries are in each lifeline is provided. The user also has the ability to navigate to their favorite entries by clicking the “Favorites” button.



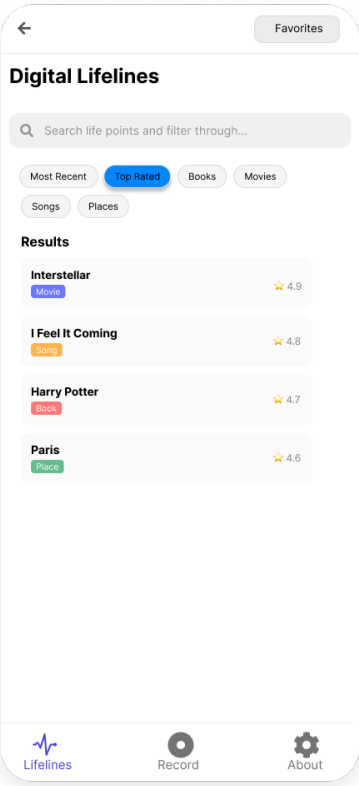
When a user wants to record an entry they can click “Add Entry” on the respective lifeline’s page. They can also click “Record” in the bar at the bottom of the screen. It’ll take them to a “Record entry” screen, where they can fill in the fields that they specified when they imported the respective JSON file or used the GUI. The “Lifeline” field is autofilled based on where they click in from. But the user can adjust the field if they so choose. The user can also mark the entry as a favorite if they want to.



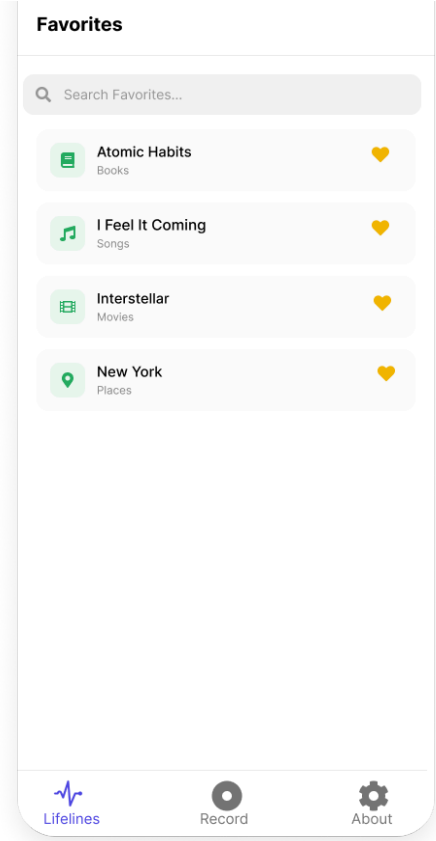
This is an example of an experience in the “Movies” category. Depending on what the user specified for fields, the entry may show up differently than as appears here. Here, the user records a title, Date Added, Last Watched, Genre, and Description.

Category/timeline name is recorded for all entries.

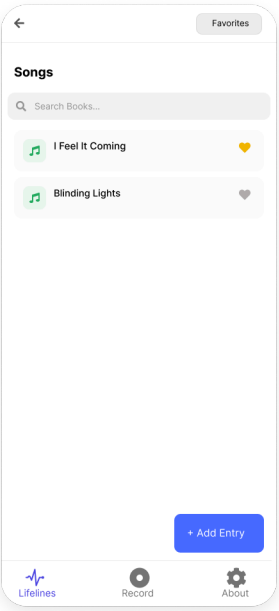
Users have the option to edit or delete the entry.

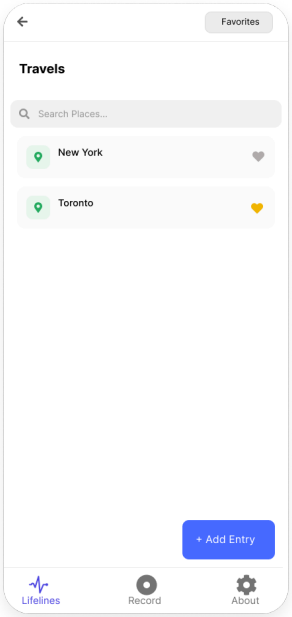


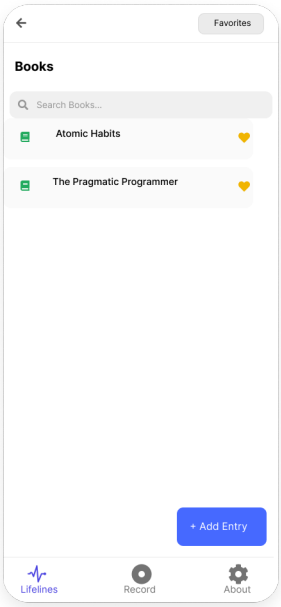
After a user adds entries, they can search for specific ones on the home page. They can either sort by Most Recent (for any entry with a date data type), Top Rated (for any entry with a rating data type), or unique categories such as books/movies/songs/places, etc. If the user selected “Top Rated” then only ratings would appear on the right. If the user selected “Most Recent” then date information would appear on the right. Users will have this view whenever they click on the search bar, and not just on homepages but any page with the search bar.

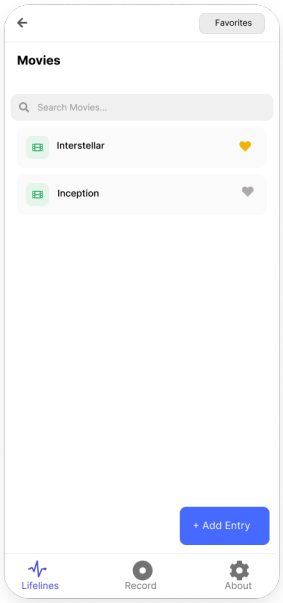


A user can also “favorite” any entry by clicking the heart. All favorite entries will appear on the “Favorites” page. Favorites will be sorted alphabetically. Categories are shown in the subheader fields. Unclicking the heart will “unfavorite” the entry and remove it from the “Favorites” page.

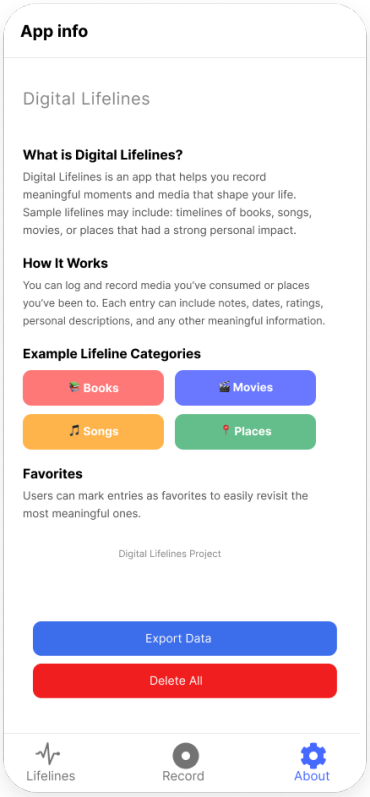








These are separate views that the user can see depending on the lifeline they navigate to. The lifeline will display information in Title header fields, as well as the option to “favorite” items. On each page, the user can add more entries through a GUI interface.



The app also provides a little description of what the Digital Lifelines app is in order to give more context about the app.

Users have the ability to export all their data in a JSON file to their local device, if they so choose. They can also delete all their data, allowing them to be fully in control of it.
